- India
- Japan
- United Kingdom
- United States

METRIC

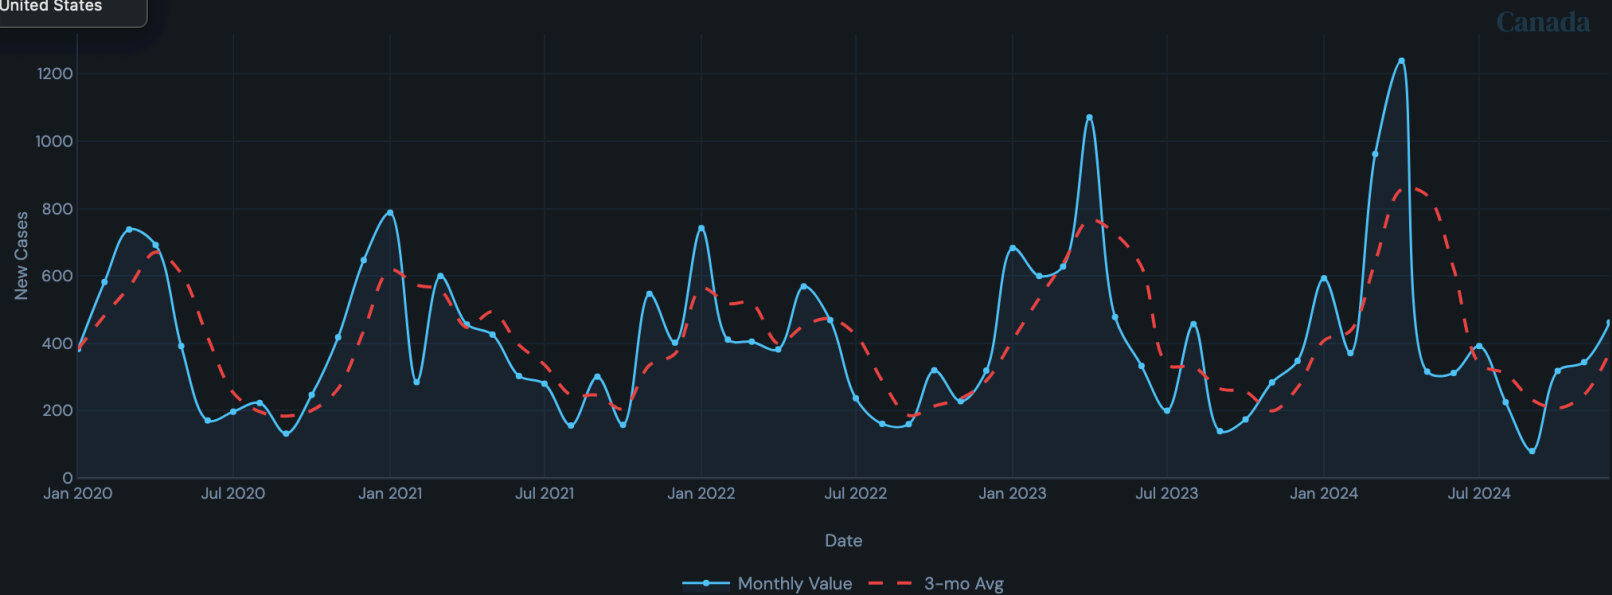

New Cases

Vaccinations

Deaths

SMOOTH

☐ 3-month rolling avg

Monthly aggregated values from the COVID_Country_Sample dataset (Our World in Data style). Spikes have been capped at the 99th-percentile to reduce data artifacts. Toggle the 3-month rolling average for a smoother trend line. Missing vaccination values in 2020 are treated as 0.

Wave Patterns

All five countries went through multiple waves between 2020 and 2024, though the timing and intensity varied. Every country's single highest monthly case count falls in the 2023 to 2024 period, suggesting the largest recorded surges came later in the pandemic. The United Kingdom stands out noticeably, with its November 2023 peak roughly double that of the next highest country. Canada, the US, India, and Japan all show smaller but consistent multi-wave patterns throughout the full period.

Vaccination Roll-out

All five countries had zero vaccinations recorded through all of 2020, with roll-outs beginning in 2021 across the board. From there the scale differs quite a bit. India's monthly numbers are far higher than the others given its population size, while Canada, the US, and the UK climbed more gradually from early to mid 2021. Japan's ramp-up started a bit later but picked up quickly once it got going.

Correlation ≠ Causation

It's worth noting that in several countries, vaccination numbers and case counts rise at the same time. That's not evidence that vaccines caused more cases. Booster campaigns were typically launched in response to new waves already underway. On top of that, seasonality, testing availability, and new variants are all happening at once, so it's rarely possible to point to a single cause. These charts are a starting point for asking questions, not drawing conclusions.

Design & Uncertainty Choices

Colour: The primary metric is drawn in blue against the dark background for contrast, with a red dashed line overlaid for the 3-month rolling average. This keeps both visible without one drowning out the other.

Spikes: Each country's values are capped at their 99th percentile to tone down extreme outliers in the sample data, while still keeping the overall shape of the trend intact.

Uncertainty: The smooth toggle lets you flip between raw monthly counts and a rolling average depending on whether you want to see the noise or the trend. Vaccination values before any roll-out began are filled in as 0, which makes sense given that no programme was in place yet.
